

How to configure the switch model in a distribution box

AI Overview

Configuring a distribution switch involves connecting via console, setting up VLANs, assigning IP addresses, and linking access switches for proper network traffic aggregation.

Step 1: Connect to the Switch Use a console cable (often a rollover cable) to connect your computer to the switch. Open a terminal emulator like PuTTY and select the appropriate serial connection speed (commonly 9600 bps) to access the switch CLI (Command Line Interface) for configuration.

Step 2: Initial Setup Power on the switch and verify that all indicator lights are functioning. Erase previous configurations if using a spare switch (e.g., delete flash:vlan.dat on Cisco switches) to start fresh. Enter privileged EXEC mode by typing enable and then access Global Configuration Mode with configure terminal.

Step 3: Set Hostname and Domain Assign a hostname to identify the switch in the network and configure a domain name if required. This helps in managing multiple switches and VTP (Virtual Trunking Protocol) domains.

Step 4: Configure VLANs Create VLANs for different network segments using commands like vlan and assign names. For distribution switches connected to routers, configure Layer 3 interfaces for each VLAN (e.g., set interface vlan.0) to allow IP routing. Ensure that VLANs on access switches match the distribution switch configuration for proper traffic forwarding.

Step 5: Assign IP Addresses Assign an IP address to the management VLAN to allow remote management via Telnet, SSH, or web interface. Example: interface vlan 1 followed by ip address 192.168.1.1 255.255.255.0.

Step 6: Configure Access and Security Set enable passwords and console/Telnet passwords to secure access. Optionally, configure AAA servers for centralized authentication. Limit which IP addresses can access the switch management interface.

Step 7: Connect Access Switches Aggregate...
