

How to insert indoor fiber optic cables into the splice box

AI Overview

Proper insertion of indoor fiber optic cables into a splice box involves careful cable preparation, routing, splicing, and secure placement in the splice tray to maintain signal integrity and prevent damage.

Step 1: Mount the Splice Box Choose a suitable location on the wall, ensuring it is accessible for maintenance and away from moisture or heat sources. Mark screw holes using a level, drill pilot holes, and insert anchors if needed. Secure the box with screws, avoiding over-tightening, especially for plastic enclosures.

Step 2: Prepare the Fiber Cables Strip the outer jacket of the indoor fiber cable carefully, exposing the buffer and coating layers without nicking the glass core. Clean the exposed fiber with a lint-free cloth and appropriate cleaning solution to remove dust and debris. Leave a service loop of 10–15 cm inside the box to allow flexibility for splicing and future maintenance.

Step 3: Insert the Cable into the Box Feed the prepared cable through the designated entry port or grommet. Secure the cable using internal clips or clamps to prevent movement. Ensure the cable is routed without sharp bends, maintaining a minimum bend radius of 30 mm to avoid signal loss or fiber breakage.

Step 4: Splice the Fibers For mechanical splices: insert the cleaved fiber ends into the splice and lock them in place. For fusion splices: use a fusion splicer to join fibers, then protect the splice with a heat-shrink sleeve. Place the completed splices into the splice tray, coiling any excess fiber neatly to avoid stress or tangling.

Step 5: Organize and Close the Box Arrange all fibers and splices to prevent tight bends and ensure easy access for future maintenance. Trim excess cable ties and secure the tray lid. If multiple trays are used, stack them according to the box's capacity, ensuring each tray is accessible like turning a page in a book. Close and lock the box cover to protect fibers from du...
